## Polymerization of Fluorinated Diacetylenes!

Kurt Baum, Paul G. Cheng, Ronald J. Hunadi and Clifford D. Bedford

Fluorochem, Inc., Azusa, California 91702

#### Synopsis

Perfluoroalkylene diacetylenes, HCEC-(CF2)n-CECH, underwent thermal polymerization at 250-350 °C to give glassy polymers stable to 450 °C. Partial polymerization of the volatile monomers gave oligomers that are processable at atmospheric pressure. Polymers with similar thermal stability were obtained by transition-metal-catalyzed polymerization of the monomers at moderate temperatures.

#### INTRODUCTION

There has been extensive interest in recent years on the application of acetylene-terminated monomers and oligomers for the preparation of thermally stable polymers. Systems that have been studied include polyphenylenes, imides, phenylquinoxalines, sulfones and triazines. The acetylene groups undergo thermal polymerization to give linking groups with high thermal stability.

ANTONIO CONTRACTOR CON

Fluorocarbons comprised another structure class that appeared to be potentially useful for this approach. Fluoropolymers possess useful stability, dielectric, and water repelency properties, but methods for the preparation of cross-linked, castable matrices are not generally available. With the objective of providing starting materials for this purpose, we developed synthesis procedures for perfluoroalkylene diacety-lenes,  $HC = C(CF_2)_n C = CH^7$ . The preferred synthetic route for  $HC = C(CF_2)_n C = CH$  and higher homologs is outlined below.

 $CF_2 = CF_2 + I_2 \longrightarrow I(CF_2)_n I$   $I(CF_2)_n I + Me_3 SiC = CSiMe_3 \longrightarrow Me_3 SiC = C(CF_2)_n C = CSiMe_3$   $Me_3 SiC = C(CF_2)_n C = CSiMe_3 + KF \longrightarrow HC = C(CF_2)_n C = CH$ 

The preparation of HC=C(CF<sub>2</sub>)<sub>6</sub>C=CH by this method was complicated by the formation of a cyclic product, and an alternate procedure consisting of addition of the fluorocarbon diiodide to trimethylsilylacetylene, dehydrohalogenation and desilylation was used.<sup>7</sup>

#### EXPERIMENTAL

Proton and fluorine NMR spectra were obtained with a Varian T-60 spectrometer. Mass spectra were obtained using a AEI MS-9 instrument. Molecular weights were obtained with a Mechrolab vapor phase osmometer. Elemental analysis was carried out by Galbraith Analytical Laboratory, Knoxville, Tenn. or Spang Microanalytical Laboratory, Eagle Harbor, Mich. Perfluoroalkylene diacetylenes were prepared by the procedures reported previously.

## 1H-Perfluoro-1-dodecyne

A mixture of 100 g (0.155 mol) of perfluorodecyl iodide and 58 g (0.34 mol) of bis(trimethylsilyl)acetylene was sealed in a heavy-wall glass ampule and heated at 220 °C for 48 h. Distillation gave 60 g of crude 1-(trimethylsilyl)perfluore-1-dodccyne as a red oil, bp 150-160 °C (2 mm). This material was stirred with 100 g of potassium fluoride dihydrate in 400 mL of methanol for 16 h. The mixture was diluted with 200 mL of saturated sodium chloride solution and was extracted with 500 mL of ether. The ether solution was dried over magnesium sulfate and distilled to give 25 g (30% based on perfluorodecyl iodide) of 1H-perfluoro-1-dodecyne, bp 35 °C (2 mm), mp 24-25 °C: III NMR 6 2.95 (t, JMF = 5 Hz); IPF NMR \$\phi\$ 86.2 (t, 3 F, J = 10 Hz, CF2), 103 (m 2 F, CF2CEC), 123-

126 (m, 14 F, CF2), 129 (m, 2 F, CF2CF3).

CONTROL CONTROL REGISTRAL PASSECO, REGISTRAL ANNUAL ANTIGER CONTROL

Catalytic Polymerization of 1H,12H-Perfluoro-1,11-dodecadiyne

A mixture of 2.0 g (4.4 mmol) of 1H,12H-Perfluoro-1,11-dodecadiyne

and 10 mg of bis(benzonitrile)palladium (II) chloride was heated in a

sealed glass tube, with occasional shaking, at 120 °C for 1 h. A brown

rubbery resin was obtained. An identically prepared sealed sample heated

for an additional 12 h period at 150 °C gave a dark glassy polymer.

#### RESULTS AND DISCUSSION

Preliminary thermal polymerization studies of the fluorinated diacetylenes were carried out using HC=C(CF2)\*C=CH, HC=C(CF2)\*C=CH and HC=C(CF2)\*\*C=CH. Samples were heated in sealed tubes at 250 °C to give clear hard polymers, yellow to amber in color. DSC analysis\* of the samples showed symmetrical exotherms at 350 °C, with no evidence of decomposition to 450 °C. Repetition of the scans showed only endotherms at 106 to 120 °C, believed to represent glass transition temperatures.

TGA showed initiation of weight loss at 450 °C. The 350 °C exotherm was ascribed to the completion of polymerization of uncured sites, confirmed by the observation of acetylenic absorbtion in the IR spectra (3318 and 2145 cm<sup>-1</sup>) of the original polymer. The HC=C(CF2)\*\*C=CH polymer showed a critical surface tension of 21.6 dynos/cm, and water absorbtion determi-

nation over a 6-month period was negative. A swelling experiment with Freon 113 showed 12% absorbtion in 90 hrs.

Because HC=C(CF<sub>2</sub>)<sub>6</sub>C=CH is more readily available in quantity than its homologs, and this material was used in subsequent work. A problem in practical applications of this diacetylene is that its volatility at the temperatures required for thermal polymerization would require the use of pressurized containers for the fabrication of samples. One way to circumvent this problem is to carry out the polymerization in sealed containers to only a low degree of completion with the objective of preparing fluid or easily processable oligomers with sufficiently low volatility that final cure can be carried out at atmospheric pressure.

The polymerization of HC=C(CF2)8C=CH was controlled adequately at 250 °C in sealed tubes, and after 41 h, 68% of the monomer was consumed. Removal of the unreacted monomer under vacuum left a viscous oil with a VPO molecular weight of four monomer units. The oligomer was then cured at atmospheric pressure by heating at 250 °C for several days to give a polymer with similar appearance and thermal properties to that obtained by polymerization of the monomer in sealed tubes.

processor services respected to the service of the services of

Another approach to applying the volatile diacetylene for molding or coating applications is to use catalysts to lower the polymerization temperature. The cyclotrimerization and oligomerization of 3,3,3-tri-fluoropropyne with metal carbonyl catalysts has been reported, and a number of catalyst systems have been used for similar reactions of non-fluorinated aromatic and aliphatic acetylenes. Consequently, we initiated qualitative screening studies to determine the effectiveness of some available catalysts for the polymerization of HCTC(CF2)sCTCH. The results are summarized in Table 1.

# Table I. Catalyst Screening

Conditions: 1 wt% catalyst heated with HC=C(CF2)aC=CH 4 hrs at 140 °C ++ sample solidified; + sample became viscous; - no change Cp = cyclopentadienyl; acac = acetylacetonate

NiBr <sub>2</sub> ·NaBH <sub>4</sub>	
Ni I2 · PPH3	+
Ni(Ph <sub>3</sub> P) <sub>2</sub> (CO) <sub>2</sub>	+

Of the catalysts tested, PdCl<sub>2</sub>(PhCN)<sub>2</sub> was the most effective, and as little as 0.1 wt% was sufficient to promote polymerization. With a 1% catalyst level, solidification took place in 2 days at ambient temperature, in 2-3 hrs at 80 °C and in minutes at 130 °C. The catalysts, Ni(acac)<sub>2</sub> and Mo(CO)<sub>6</sub> were less effective than PdCl<sub>2</sub>(PhCN)<sub>2</sub>, but they also produced polymers with appearance similar to that of the thermally produced polymer. On the other hand, Ni(Ph<sub>3</sub>P)<sub>2</sub>(CO)<sub>2</sub> and CpCo(CO)<sub>2</sub> gave tarry products. Because of the effectiveness of PdCl<sub>2</sub>(PhCN)<sub>2</sub> for our system, further work was carried out with this catalyst, which has been reported to trimerize alkynes selectively to benzenes.<sup>12</sup>

Cured samples of the catalyzed polymer were similar to those produced thermally in that they had a glassy appearance and were brittle.

DSC curves of the two types of polymer were essentially identical. To

obtain additional information about the polymeriaztion reactions, model studies were carried out using CF<sub>3</sub>(CF<sub>2</sub>)<sub>9</sub>C<sub>2</sub>CH. Heating a sample of this monoacetylene with PdCl<sub>2</sub>(PhCN)<sub>2</sub> at 110 °C for 5 h gave a 95% yield of an oil, identified by molecular weight, elemental analysis, and mass spectroscopy as a trimer of the starting material.

Also, CF<sub>3</sub>(CF<sub>2</sub>)<sub>9</sub>C=CH was heated under conditions used for the thermal polymerization of the diacetylenes, 260 °C for 40 h. The product was a sublimable solid with a molecular weight by VPO of four monomer units.

The brittleness of the polymers is attributed to the high degree of cross-linking, and would be expected to be lessened by copolymerizing a monoacetylene with the diacetylene. Mechanical properties of the palladium-catalyzed homopolymers and several copolymers were determined by the three-point bending method<sup>13</sup>, and are summarized in Table II. Copolymers of HC=C(CF<sub>2</sub>)<sub>0</sub>C=CH were obtained with PdCl<sub>2</sub>(PhCN)<sub>2</sub> as the catalyst and CF<sub>3</sub>(CF<sub>2</sub>)<sub>0</sub>C=CH as the monofunctional component. A sample based on 28 mole % monoacetylene was a hard resin similar to the diacetylene homopolymer, but somewhat less brittle. However, a sample prepared with 57 % of the monoacetylene was flexible and rubbery. Tensile moduli of the copolymers and the homopolymer are in agreement with these observations.

Tensile moduli for the homopolymer at temperatures to 200 °C were also determined. There is no significant discontinuity at the temperature of the DTA endotherm (118 °C).

Table II. Tensile Moduli
